# Euclidean Embeddings of Weighted Graphs

## High-Level Introduction

The embedding problem is the following:

### Main Problem

*Given a weighted graph  $G = (\mathcal{V}, W)$  with  $n$  nodes, find a dimension  $d$  and a set of  $n$  points  $\{y_1, \dots, y_n\} \subset \mathbb{R}^d$  such that  $W_{i,j} = \varphi(\|y_i - y_j\|)$  for some monotonically decreasing function  $\varphi$ .*

# Euclidean Embeddings of Weighted Graphs

## High-Level Introduction

The embedding problem is the following:

### Main Problem

*Given a weighted graph  $G = (\mathcal{V}, W)$  with  $n$  nodes, find a dimension  $d$  and a set of  $n$  points  $\{y_1, \dots, y_n\} \subset \mathbb{R}^d$  such that  $W_{i,j} = \varphi(\|y_i - y_j\|)$  for some monotonically decreasing function  $\varphi$ .*

Approaches:

- 1 **Nearly Isometric Embeddings.** Three steps: (1) convert weights into geometric distances; (2) solve a SDP optimization problem; (3) perform a factorization (PCA) of the solution.
- 2 **Laplacian Eigenmaps.** Three steps: (1) Construct the symmetric normalized weighted Laplacian matrix; (2) Solve for a set of eigenvectors; (3) Perform embedding.

# Distance Models for Weighted Graphs

Let  $W = (W_{i,j})_{1 \leq i,j \leq n}$  be a known weight matrix.

Most frequently employed models:

- 1 Exponential Law:  $W_{i,j} = e^{-d_{i,j}^2/\sigma^2}$ .
- 2 Power Law:  $W_{i,j} = \frac{C}{d_{i,j}^p}$ .

where  $d_{i,j}$  denotes the distance between points  $i$  and  $j$ .  
 $\sigma$ ,  $C$ ,  $p$  are parameters.

# Distance Models for Weighted Graphs

Let  $W = (W_{i,j})_{1 \leq i,j \leq n}$  be a known weight matrix.

Most frequently employed models:

- ① Exponential Law:  $W_{i,j} = e^{-d_{i,j}^2/\sigma^2}$ .
- ② Power Law:  $W_{i,j} = \frac{C}{d_{i,j}^p}$ .

where  $d_{i,j}$  denotes the distance between points  $i$  and  $j$ .  
 $\sigma$ ,  $C$ ,  $p$  are parameters.

Without loss of generality one can scale the coordinates (points) and absorb global constants. Hence we can assume  $\sigma = 1$ ,  $C = 1$ .

Therefore one can compute the estimated distances by:

$$d_{i,j} = \begin{cases} -\log(W_{i,j}) & \text{exponential law} \\ \left(\frac{1}{W_{i,j}}\right)^{1/p} & \text{power law} \end{cases}$$

# Isometric Embeddings with Full Data

Converting pairwise distances into the Gram matrix

Solve the geometric problem:  $\|y_i - y_j\|^2 = d_{i,j}^2$ ,  $1 \leq i, j \leq n$ .

Let  $S = (S_{i,j})_{1 \leq i, j \leq n}$  denote the  $n \times n$  symmetric matrix of pairwise distances:

$$S_{i,j} = d_{i,j}^2, S_{i,i} = 0$$

Denote by  $\mathbf{1}$  the  $n$ -vector of 1's (the Matlab *ones*( $n, 1$ )). Let  $\nu = (\|y_i\|^2)_{1 \leq i \leq n}$  denote the unknown  $n$ -vector of squared-norms. Finally, let  $G = (\langle y_i, y_j \rangle)_{1 \leq i, j \leq n}$  denote the Gram matrix of scalar products between

We can remove the translation ambiguity by fixing the center:

$$\sum_{i=1}^n y_i = 0$$

# Isometric Embeddings with Full Data

Converting pairwise distances into the Gram matrix

Expand the square:

$$d_{i,j}^2 = \|y_i - y_j\|^2 = \|y_i\|^2 + \|y_j\|^2 - 2\langle y_i, y_j \rangle$$

Rewrite the system as:

$$2G = \nu \cdot \mathbf{1}^T + \mathbf{1} \cdot \nu^T - S \quad (*)$$

The center condition reads:  $G \cdot \mathbf{1} = 0$ , which implies:

$$0 = 2n\nu^T \cdot \mathbf{1} - \mathbf{1}^T \cdot S \cdot \mathbf{1}$$

Let  $\rho := \nu^T \cdot \mathbf{1} = \sum_{i=1}^n \|y_i\|^2$ . We obtain:

$$\rho = \frac{1}{2n} \mathbf{1}^T \cdot S \cdot \mathbf{1} = \frac{1}{2n} \sum_{i=1}^n \sum_{j=1}^n d_{i,j}^2$$

$$\nu = \frac{1}{n} (S \cdot \mathbf{1} - \rho \mathbf{1}) = \frac{1}{n} (S - \rho I) \cdot \mathbf{1}$$

that you substitute back into (\*).

# Isometric Embeddings with Full Data

Converting pairwise distances into the Gram matrix: Algorithm

## Algorithm

*Input: Symmetric matrix of pairwise distances  $S = (d_{i,j}^2)_{1 \leq i,j \leq n}$ .*

① *Compute:*

$$\rho = \frac{1}{2n} \mathbf{1}^T \cdot S \cdot \mathbf{1} = \frac{1}{2n} \sum_{i=1}^n \sum_{j=1}^n d_{i,j}^2$$

② *Set:*

$$\nu = \frac{1}{n} (S \cdot \mathbf{1} - \rho \mathbf{1}) = \frac{1}{n} (S - \rho I) \cdot \mathbf{1}$$

③ *Compute:*

$$G = \frac{1}{2n} (S - \rho I) \mathbf{1} \cdot \mathbf{1}^T + \frac{1}{2n} \mathbf{1} \cdot \mathbf{1}^T (S - \rho I) - \frac{1}{2} S.$$

*Output: Symmetric Gram matrix  $G$*

# Isometric Embeddings with Full Data

## Factorization of the $G$ matrix

In the absence of noise (i.e. if  $S_{i,j}$  are indeed the Euclidean distances), the Gram matrix  $G$  should have rank  $d$ , the minimum dimension of the isometric embedding.

If  $S$  is noisy, then  $G$  has approximate rank  $d$ .

To find  $d$  and  $Y$ , the matrix of coordinates, perform the eigendecomposition:

$$G = Q\Lambda Q^T$$

where  $\Lambda$  is the diagonal matrix of eigenvalues, ordered monotonically decreasing. Choose  $d$  as the number of significant positive eigenvalues (i.e. truncate to zero the negative eigenvalues, as well as the smallest positive eigenvalues).

# Isometric Embeddings with Full Data

## Factorization of the $G$ matrix

Then we obtain an approximate factorization of  $G$  (exact in the absence of noise):

$$G \approx Q_1 \Lambda_1 Q_1^T$$

where  $Q_1$  is the  $n \times d$  submatrix of  $Q$  containing the first  $d$  columns.

Set  $Y = \Lambda_1^{1/2} Q_1^T$ , so that  $G \approx Y^T Y$ .

The  $d \times n$  matrix  $Y$  contains the embedding vectors  $y_1, \dots, y_n$  as columns:

$$Y = [y_1 | y_2 | \dots | y_n].$$

# Isometric Embeddings with Full Data

Gram matrix factorization: Algorithm

## Algorithm

*Input: Symmetric  $n \times n$  Gram matrix  $G$ .*

- ① *Compute the eigendecomposition of  $G$ ,  $G = Q\Lambda Q^T$  with diagonal of  $\Lambda$  sorted in a descending order;*
- ② *Determine the number  $d$  of significant positive eigenvalues;*
- ③ *Partition*

$$Q = [Q_1 \quad Q_2] \quad , \text{ and } \Lambda = \begin{bmatrix} \Lambda_1 & 0 \\ 0 & \Lambda_2 \end{bmatrix}$$

*where  $Q_1$  contains the first  $d$  columns of  $Q$ , and  $\Lambda_1$  is the  $d \times d$  diagonal matrix of significant positive eigenvalues of  $G$ .*

- ④ *Compute:*

$$Y = \Lambda_1^{1/2} Q_1^T$$

*Output: Dimension  $d$  and  $d \times n$  matrix  $Y$  of vectors  $Y = [y_1 | \cdots | y_n]$*

# Isometric Embeddings with Partial Data

## Dimension estimation

Consider now the case that only a subset of the pairwise distances are known, say  $\Theta$ . Assume only  $m$  distances (out of  $n(n-1)/2$  possible values) are known. We want to estimate  $G$ , and then use the factorization algorithm to compute the embedding.

### Remark

*Minimum number of measurements:  $m \geq \frac{d(d+1)}{2}$ , the dimension of the Lie group of Euclidean transformations: translations ( $\mathbb{R}^d$  of dimension  $d$ ) and orthogonal group ( $O(d)$  of dimension  $d(d-1)/2$ , the dimension of the Lie algebra of anti-symmetric matrices).*

# Isometric Embeddings with Partial Data

## Linear constraints

Given any set of vectors  $\{y_1, \dots, y_n\}$  and their associated matrix  $Y = [y_1 | \dots | y_n]$  their invariant to the action of the Euclidean transformations (translations, rotations, and permutations) is the Gram matrix of the centered system:

$$G = \left(I - \frac{1}{n} \mathbf{1} \cdot \mathbf{1}^T\right) Y^T Y \left(I - \frac{1}{n} \mathbf{1} \cdot \mathbf{1}^T\right).$$

On the other hand, distance between points  $i$  and  $j$  can be computed by:

$$d_{i,j}^2 = \|y_i - y_j\|^2 = G_{i,i} - G_{i,j} + G_{j,j} - G_{j,i} = e_{ij}^T G e_{ij}$$

where

$$e_{ij} = \delta_i - \delta_j = [0 \dots 0 \ 1 \dots -1 \ 0 \dots 0]^T$$

where 1 is on position  $i$ ,  $-1$  is on position  $j$ , and 0 everywhere else.

# Isometric Embeddings with Partial Data

## The SDP Problem

Reference [10] proposes to find the matrix  $G$  by solving the following Semi-Definite Program:

$$\begin{aligned} \min \quad & \text{trace}(G) \\ \text{subject to} \quad & G = G^T \geq 0 \\ & |\langle Ge_{ij}, e_{ij} \rangle - d_{i,j}^2| \leq \varepsilon, \quad (i, j) \in \Theta \end{aligned}$$

Here  $\varepsilon$  is the maximum tolerance noise level. The trace plays little role in this optimization. Essentially this is a feasibility problem: Decrease  $\varepsilon$  to the minimum value where a feasible solution exists. With probability 1 that is unique.

How to do this: Use CVX with Matlab.

# Convex Sets. Convex Functions

A set  $S \subset \mathbb{R}^n$  is called a *convex set* if for any points  $x, y \in S$  the line segment  $[x, y] := \{tx + (1-t)y, 0 \leq t \leq 1\}$  is included in  $S$ ,  $[x, y] \subset S$ .

A function  $f : S \rightarrow \mathbb{R}$  is called *convex* if for any  $x, y \in S$  and  $0 \leq t \leq 1$ ,  $f(tx + (1-t)y) \leq tf(x) + (1-t)f(y)$ .

Here  $S$  is supposed to be a convex set in  $\mathbb{R}^n$ .

Equivalently,  $f$  is convex if its epigraph is a convex set in  $\mathbb{R}^{n+1}$ . Epigraph:  $\{(x, u) ; x \in S, u \geq f(x)\}$ .

A function  $f : S \rightarrow \mathbb{R}$  is called *strictly convex* if for any  $x \neq y \in S$  and  $0 < t < 1$ ,  $f(tx + (1-t)y) < tf(x) + (1-t)f(y)$ .

# Convex Optimization Problems

The general form of a convex optimization problem:

$$\min_{x \in S} f(x)$$

where  $S$  is a closed convex set, and  $f$  is a convex function on  $S$ .

Properties:

- 1 Any local minimum is a global minimum. The set of minimizers is a convex subset of  $S$ .
- 2 If  $f$  is strictly convex, then the minimizer is unique: there is only one local minimizer.

In general  $S$  is defined by equality and inequality constraints:

$S = \{g_i(x) \leq 0, 1 \leq i \leq p\} \cap \{h_j(x) = 0, 1 \leq j \leq m\}$ . Typically  $h_j$  are required to be affine:  $h_j(x) = a^T x + b$ .

# Convex Programs

The hierarchy of convex optimization problems:

- ① Linear Programs: Linear criterion with linear constraints
- ② Quadratic Programs: Quadratic Criterion with Linear Constraints;  
Quadratically Constrained Quadratic Problems (QCQP);  
Second-Order Cone Program (SOCP)
- ③ Semi-Definite Programs(SDP)

Typical SDP:

$$\begin{aligned} & \min && \text{trace}(XA) \\ & X = X^T \geq 0 \\ & \text{trace}(XB_k) = y_k, \quad 1 \leq k \leq p \\ & \text{trace}(XC_j) \leq z_j, \quad 1 \leq j \leq m \end{aligned}$$

## CVX

## Matlab package

Downloadable from: <http://cvxr.com/cvx/> . Follows "Disciplined" Convex Programming – à la Boyd [2].

```
m = 20; n = 10; p = 4;
A = randn(m,n); b = randn(m,1);
C = randn(p,n); d = randn(p,1); e = rand;
```

```
cvx_begin
```

```
    variable x(n)
```

```
    minimize( norm( A * x - b, 2 ) )
```

```
    subject to
```

```
        C * x == d
```

```
        norm( x, Inf ) <= e
```

```
cvx_end
```

$$\begin{array}{ll} \min & \|Ax - b\| \\ & Cx = d \\ & \|x\|_\infty \leq e \end{array}$$
